25

26 Abstract

Spain.

27 The family Chlamydiaceae currently comprises a single genus Chlamydia, with 11 validly published species and seven 28 more taxa. It includes the human pathogens Chlamydia (C.) trachomatis, C. pneumoniae and C. psittaci, a zoonotic 29 agent causing avian chlamydiosis and human psittacosis, as well as other proven or potential pathogens in ruminants, 30 birds, snakes, reptiles and turtles. During routine testing of 15 apparently healthy captive flamingos in a zoo in 2011, an 31 atypical strain of Chlamydiaceae was detected by real-time PCR of cloacal swab samples. Sequence analysis of the 32 16S rRNA gene revealed high similarity to the uncultured Chlamydiales bacterium clone 122, which previously had 33 been found in gulls. As more samples were collected during annual campaigns of the flamingo ringing program in 34 southern France from 2012 to 2015, Chlamydiaceae-specific DNA was detected by PCR in 30.9% of wild birds. From 35 these samples, three strains were successfully grown in cell culture. Ultrastructural analysis, comparison of 16S and 36 23S rRNA gene sequences, whole-genome analysis based on de novo hybrid-assembled sequences of the new

37 strains as well as subsequent calculation of taxonomic parameters revealed that the relatedness of the flamingo

^{8 &}lt;sup>1</sup> University Paris-Est, Anses, Animal Health Laboratory, Bacterial Zoonoses Unit, Maisons-Alfort, France.

38 isolates to established members of the family Chlamydiaceae was sufficiently distant to indicate that the three strains

39 belong to two distinct species within a new genus. Based on these data, we propose the introduction of *Chlamydiifrater*

- 40 gen. nov., as a new genus, and Chlamydiifrater phoenicopteri sp. nov. and Chlamydiifrater volucris sp. nov., as two
- 41 new species of the genus.

 rRNA gene sequence; Comparative genome analysis

45

46 Introduction47

48 The family Chlamydiaceae currently comprises a single genus, Chlamydia, with 11 validly published species and an 49 additional seven proposed species, four of which at Candidatus rank. These obligate intracellular bacteria include the 50 zoonotic agent Chlamydia (C.) psittaci, as well as the recently discovered C. avium, C. gallinacea and C. buteonis that 51 all have a preference for avian hosts [42]. These four avian chlamydiae are now easily identifiable thanks to molecular 52 tools designed for their rapid and specific detection [35, 54, 55]. However, several studies have reported the detection 53 of non-classified chlamydial organisms in avian samples. Since chlamydiae have been detected in 465 different bird 54 species [18], it is not surprising that our knowledge on the diversity of chlamydial species occurring in wild birds is 55 steadily expanding. For instance, isolation of two related strains from ibis specimens led to the proposal of Candidatus 56 C. ibidis as an additional genus member [51]. A new species found in hawks, C. buteonis, has just been reported [23]. 57 In addition, C. abortus strains were recently isolated from wildfowl [48]. From non-avian hosts, recent descriptions of 58 new taxa include C. serpentis and C. poikilothermis from snakes [46], the Candidatus species of C. sanzinia and C. 59 corallus from reptiles [49], as well as C. testudinis from tortoises [22].

The high genetic diversity of chlamydial strains of avian origin belonging to the order *Chlamydiales* has been mentioned in various studies [1, 3, 17, 56]. The main obstacle to comprehensive genetic characterization of these chlamydial organisms is their obligate intracellular lifestyle, which requires cell culture for recovery of isolates. As numerous failed attempts in various experienced laboratories have shown, these atypical chlamydial strains are extremely difficult to grow. As a consequence, most of the studies published so far have been unable to classify and comprehensively characterize atypical avian chlamydial organisms.

In the present paper, we report the identification and description of new chlamydiae from captive and wild flamingos. Initially, diagnostic testing during their introduction into a zoo revealed the occurrence of an atypical chlamydial agent. Follow-up investigations led to the isolation and detailed characterization of three chlamydial strains, which will be classified as two new species belonging to a new genus of the family *Chlamydiaceae*.

70

71 Materials and Methods

73 Samples

74 Cloacal swabs were taken from both captive (Phoenicopterus chilensis) and wild birds (Phoenicopterus roseus).

75 Captive flamingos sampled in 2011 were from the Bioparc zoo (Doué-la-Fontaine, France) (n=18) and those sampled

- in 2014 were from the Paris Zoo (n=37). Wild specimens (n= 404) were collected during the annual round-ups that are
- organized each summer in the Camargue region of France for the purpose of banding flamingos chicks. In 2012, 2013
- and 2015, catches took place in the Étang du Fangassier, whereas in 2014, due to the nesting change of the group,
- 79 they took place in the saline of Aigues-Mortes near the Mediterranean coast of Southern France.
- 80 Duplicate swabs were collected from each bird. The first swab was stored dry at -20°C until being subjected to DNA
- 81 extraction and the other was stored in SPG medium [44] at 80°C until inoculation for isolation. Key data are
- 82 summarized in Table 1.
- 83

84 Direct detection of Chlamydiaceae DNA from avian samples

Cloacal swabs were subjected to DNA extraction using a QIAamp DNA Mini Kit, following the buccal swab protocol (Qiagen, Courtaboeuf, France). DNA was eluted with 150 µL of AE buffer and stored at -20°C before analysis. A *Chlamydiaceae*-specific real-time PCR targeting the 23S rRNA gene was used in this study [9]. An exogenous positive

- 88 control was included in each sample to test for the presence of PCR inhibitors (Exogenous internal positive control,
- 89 TaqMan, Life technologies). All samples with a quantification cycle (Cq) over 40 were considered negatives.
- 90 PCR assays specifically identifying *C. psittaci*, *C. avium*, *C. gallinacea* or *Candidatus* C. ibidis species were conducted 91 as previously described [35, 54, 55].
- 92

93 Isolation and propagation in cell culture

94 Buffalo green monkey (BGM) cells in minimal essential medium (MEM, Lonza, France) with 5% fetal calf serum were 95 seeded into Trac bottles containing glass coverslips (Thermo Scientific, France) and incubated at 37°C with 5% CO₂ in 96 a fully humidified cabinet for 2 days. Swabs in 2 mL of SPG medium were ultrasonicated (ten 0.8s pulses at an 97 amplitude of 80%; Branson 450D Sonifier) and medium (30 to 300 µL) was inoculated into six Trac bottles with 98 confluently grown BGM monolayers. After inoculation, the bottles were centrifuged at 3000 g for 60 min at 37°C and 99 subsequently incubated for 2 h in the CO₂ cabinet. The MEM medium was then replaced with serum-free medium 100 UltraMDCK (Lonza, France) containing the antibiotics amphotericin B (2.5 µg/mL), gentamicin (10 µg/mL) and 101 vancomycin (25 µg/mL). Medium was renewed at 18 h post infection. Three days after inoculation, a single coverslip 102 was fixed with methanol, and the monolayer was stained with IMAGEN Chlamydia (Oxoid, France). A sample was 103 considered positive when inclusions of typical chlamydial morphology appeared as bright apple-green spots after a 104 maximum of two passages.

105

106 Transmission electron microscopy (TEM)

- $107 \qquad \text{BGM cells were infected with isolates 14-2711_R47 and 15-2067_O50. Infected cells were harvested at 24, 48 and 72 \\ \text{Constant} = 1000 \text{ m}^{-1} \text{ m}^{-1$
- 108 hours post-infection. After washing, cells were fixed in 2.5% glutaraldehyde in cacodylate buffer (0.1 M, pH 7.2) with
- 109 1.8% glucose for 6 h at 4°C. Then they were gently scrapped off the culture plate, transferred into an Eppendorf tube
- 110 and the fixative replaced by cacodylate buffer. For embedding, cells were centrifuged for 5 min at 1.500 x g. The cell
- pellet was embedded in 2% agarose and sectioned to 1 mm³ cubes. Cubes were post-fixed in 2% osmium tetroxide,
- dehydrated in acetone and embedded in araldite Cy212. Relevant areas were selected in Toluidine blue-stained semi-

113 thin sections. Ultrathin sections (85 nm) were stained with uranyl acetate and lead citrate, examined by transmission

electron microscopy (Tecnai 12; FEI) and representative micrographs documented (TEMCAM FX416, TVIPS, Gauting,Germany).

116

117 DNA-based characterization

118 Amplifications and 16S rRNA sequence analysis

119 Primers 16S1 and rp2 were used for amplification of approximately 1500 nucleotides of the 16S rRNA gene as 120 previously described [41]. Sequences were combined in an alignment with previously published sequences relevant for 121 phylogenetic and epidemiological studies. The first 16S rRNA sequence obtained from sample 11-261_B096 was 122 searched (BLASTN) against the NCBI non-redundant nucleotide database for identification. Other sequences were 123 analyzed using the Bionumerics software package version 7.6.2 (Applied-Maths, Belgium). A similarity matrix was 124 calculated using a pairwise alignment with a Jukes and Cantor correction. A phylogenetic tree was constructed using 125 RAXML v8 [45], with the GTRGAMMA model and 1000 bootstrap replicates based on an alignment of all 16S rRNA 126 sequences using MAFFT v7 [19] The 16S rRNA nucleotide sequences of samples 11-261_B96, 13-234 I89, 13-234 127 194, 13-234 199, 13-3212 BE60, 14-2711 R45, 14-2711 R47 isolate, 14-2711 R79, 15-2711 O50 isolate, 15-128 2711 O77, 15-2711 O99 isolate have been deposited under accession numbers LR777664 to LR777674 at the ENA 129 database.

130

131 DNA preparation for genome sequencing

132 Genomic DNA of isolates 14-2711_R47, 15-2067_O50 and 15-2067_O99 was prepared from 14 mL of BGM cell 133 culture harvested from a 75-cm² culture flask. Each suspension was centrifuged at 20,000 g at 8°C for 45 min, and the 134 supernatant was discarded. The pellet was re-suspended in 40 mL of PBS buffer and centrifuged at 500 g for 15 min to 135 remove cell debris. The supernatant was transferred to a fresh tube and high-speed centrifuged as above. The pellet 136 was re-suspended in 200 µL of PBS. Prior to DNA extraction, a DNAse I (NEB, France) treatment was performed to 137 remove potential DNA from cells. Genomic DNA was extracted using the Qiamp DNA Mini kit (Qiagen, France), with an 138 additional RNase A (Roche) treatment after lysis, according to the cell protocol of the manufacturer. DNA was eluted in 139 50 µL of water and re-purified using the NEBNext Microbiome DNA enrichment kit (NEB, France).

140

141 Genome sequencing, hybrid *de novo* assembly, annotation and comparative analysis

142 Libraries were prepared using the Nextera XT kit (Illumina) and the Native barcoding genomic DNA kit (Oxford 143 Nanopore Technologies; ONT). Whole-genome sequencing was performed using the Illumina MiSeq platform and the 144 MinION with a R9.4.1 flowcell according to the manufacturers' instructions. The MiSeq run was carried out on the DNA 145 preparation, yielding paired-end reads of 150 bp using MiSeq V2 reagents. Nanopore raw signal Fast5 files were 146 basecalled and then demultiplexed using Guppy v3.4.4 (ONT). A de novo hybrid assembly was done with long reads 147 from MinION and short reads from Illumina using Unicycler v0.4.8 with default parameters [52]. Resulting contigs were 148 subsequently blasted on the nucleotide database of NCBI to remove residual mammalian sequences from cell culture 149 constituents. Assembled genomes were annotated using Prokka v1.14.5 [43]. Short reads from Illumina were mapped

150 back to the assembly using BWA v0.7.12-5 [25] and long reads from Nanopore were mapped with minimap2 v2.17-151 r941 [24]. Statistics of the assemblies were generated using Qualimap v2.2.2-dev [10]. Genome sequences of all three 152 isolates have been deposited in the ENA database under the following accession numbers: ERZ1300893 (14-153 2711 R47), ERZ1300894 (15-2067 O50), and ERZ1300895 (15-2067 O99). Illumina raw reads are available at ENA 154 under accession numbers ERR3950885 (14-2711_R47), ERR3950886 (15-2067_O50), and ERR3950887 (15-155 2067_099) and ONT raw reads under accession numbers ERR3950922 (14-2711_R47), ERR3950921 (15-156 2067 O50), and ERR3950920 (15-2067 O99).

157 For comparative genome analysis, the novel Roary ILP Bacterial Annotation Pipeline (RIBAP) was used 158 (github.com/hoelzer-lab/ribap). Based on annotations provided by Prokka, the pipeline combines various core gene 159 sets calculated by Roary [34] with a newly adapted Integer Linear Programming (ILP) algorithm [28]. The combination 160 of Roary and ILP results led to the creation of the final interactive RIBAP table, which allows systematic searches for 161 common and specific features in the genomes, as well as downloads of multiple-sequence alignments and 162 phylogenetic trees.

163 RIBAP is implemented using the workflow management system Nextflow [6] and all used tools are encapsulated in 164 Docker images [30] to allow easy installation and execution of the pipeline (see GitHub for further instructions). We ran 165 the pipeline in v0.3 from a set of three genomes of the new flamingo isolates and twelve genomes of selected type and 166 reference strains of Chlamydia spp. All 15 input genomes and the interactive RIBAP output table are available at the 167 Open Science Framework (https://osf.io/d8yk3). The following command was used to execute the pipeline: nextflow run 168 hoelzer-lab/ribap -r v0.3 --fasta '*.fasta'. The POCP values and the UpSet plots described below are based on the 169 RIBAP output and the defined homologous groups.

170

171 UpSet diagrams

172 The UpSetR package is a scalable tool for visualizing intersecting sets and their properties [4]. As an input for UpSetR,

173 we selected the homologous gene groups identified with RIBAP for the 15 input genomes. The UpSet visualization of 174 all 15 strains was restricted to the largest 40 intersecting sets.

175

176 Real-time PCR for detection of the new genus and the two new species

177 A new real-time PCR was designed to specifically detect the members of the new genus. Briefly, primers Chlfr_F (5'-178 ACCTGGTACGCTCAAGTTTTC -3'), Chlfr_R (5'- GCGTGTGTGATGAAGGCTTT -3') and probe Chlfr_P (5'-FAM-179 TCCCTTATTCCCAGGCGAAA -TAMRA-3') targeting the 16S rRNA gene locus were used in a TagMan assay. Real-180 time PCR was performed using the 2x TaqMan Fast Advanced Master Mix supplemented with ROX (Applied 181 Biosystems), 0.625 µM of each primer, 0.1 µM of probe and 2 µl of DNA sample in a 20-µl final volume. 182 Amplification was carried out on a Viia 7 thermocycler (Applied Biosystems) using the following cycling parameters:

- 183
- initial step 50°C for 2 min followed by heating at 95 °C for 20 s, and 45 cycles of 95 °C/3 s and 61 °C/30 s. The
- 184 quantification cycle (Cq) was calculated automatically. In addition, two real-time PCRs were designed to detect each
- 185 species of the new genus. For the new species comprising isolate 14-2711 R47, primers Chlfr ph F (5'-
- 186 TACAGACCAGTCGGAGCAAAA -3'), Chlfr_ph_R (5'- TTGCAGCAGCCAATGTTCTCT -3') and probe Chlfr_ph_P (5'-

FAM- TCCCTTAGGCGTGGCATCCTTCAACT -TAMRA-3') targeting the RNA polymerase sigma-54 factor gene *rpo*N were used in a TaqMan assay. For another new species comprising isolates 15-2067_O50 and 15-2067_O99, primers Chlfr_vo_F (5'- TCCTGCTCCTTGAGAAAAGCT -3'), Chlfr_vo_R (5'- CATTGTCCTTCATGCTCTCGT -3') and probe Chlfr_vo_P (5'- FAM-TCCTCTAAGACCGCCATTGCCTGATGT-TAMRA-3') targeting the *rpo*N gene of this species were designed for the species-specific TaqMan assay. Mix concentrations and cycle parameters are the same as described above except the annealing/elongation step, which is performed at 95°C for 3s and 60°C for 30 s. The specificity of each assay was evaluated on 30 samples of different *Chlamydiaceae* DNA (**Table S1**).

194

195 Phylogenetic analysis

196 A similarity matrix of the 16S and 23S rRNA genes was calculated using a pairwise alignment with a Jukes and Cantor

197 correction of the three genomes and other established species. Moreover, nine phylogenetic markers previously 198 described [36] were extracted from the 11 *Chlamydiaceae* reference sequences, from *Candidatus* C. ibidis, form the

three isolates 14-2711_R47, 15-2067_O50 and 15-2067_O99 and from seven non-Chlamydiaceae. Amino acid sequences were aligned with MAFFT v7 [19] and concatenated to build a reference phylogeny using RAxML v8 [45], with the LG+G+I model and 100 bootstrap replicates. Pairwise amino acid sequence identities were calculated based

- 202 on the MAFFT alignment using Geneious v10 (www.geneious.com).
- Plasmids of 11 *Chlamydiaceae* reference strains and the three new flamingo isolates were aligned using MUSCLE v3.8.31 [8], and a phylogenetic tree was built using RAxML v8 with the GTRGAMMA model and 100 bootstrap replicates.
- The plasmids of the three new strains were annotated manually by identifying the ORFs using Geneious v10. Each ORF was searched (BLASTX) against the NCBI non-redundant protein sequence database for annotation. Linear comparison of plasmids was constructed using Easyfig v2.2.3 [47] with the *C. psittaci* plasmid pCps6BC serving as a reference.
- 210

211 Pairwise comparison of genome sequences, percentage of conserved proteins (POCP), and average amino acid 212 identity (AAI).

- The parameters of the tetranucleotide signature frequency correlation coefficient (tetranucleotide regression) and average nucleotide identity (ANIb) were determined as described previously [38] using the program JSpecies v1.2.1 with default parameters. The percentage of conserved proteins (POCP) was calculated using a Ruby implementation of the formula given by Qin [37] (https://github.com/hoelzer/pocp) and the average amino acid identity (AAI) was calculated using the MiGA program [39].
- 218
- 219 Additional long-read-based analysis of major outer membrane protein (MOMP) and in-silico assessment
- 220 Nanopore long reads spanning the region of interest with multiple copies of *omp*A-like genes were visualized from the
- 221 long read mapped to the hybrid assembly using the matplotlib library [16]. The underlying python script can be found in
- the OSF repository (https://osf.io/zwgc9/). Besides, we performed draft assemblies for all three flamingo strains with
- the ONT long-reads only using Flye [20] to reduce errors possibly induced by an initial short-read graph as used by

224 Unicycler. First, the longest ONT reads were selected with Filtlong v0.2.0 (https://github.com/rrwick/Filtlong) to achieve 225 a coverage of approximately 100X per strain and subsequently assembled with Flye using the parameters —plasmids, 226 -meta, and a genome size of 1 Mbp. The draft assemblies were then polished in one round of Racon v1.4.7 [50] using 227 minimap2 v2.17 to align the long reads followed by a final polishing with Medaka v1.0.3 228 (https://github.com/nanoporetech/medaka) using the r941_min_high_g360 model. Sequences identified as MOMP 229 based on the Prokka annotation were extracted for each of the new Chlamydiifrater isolates. Subsequently, these 230 sequences were aligned to a full-length reference MOMP of Chlamydia pneumoniae CWL029 (AE001363.1) using 231 Mafft v7.402 with default parameters. The alignments were visualized using Clustalx 2.1.

232

233 234

231

235 Results236

237 Detection of atypical chlamydiae during routine examination of captive flamingos

238 In 2011, a flock of 15 flamingos (Phoenicopterus chilensis) was acquired by the Bioparc zoo and kept in guarantine 239 until diagnosed negative for avian chlamydiosis and other diseases. Cloacal swabs were taken from these birds and, 240 using a Chlamydiaceae-specific PCR, three samples tested positive (id 11-261) in a private diagnostic laboratory. In 241 the National Reference Laboratory, positivity for the family Chlamydiaceae was confirmed, but these samples tested 242 negative for C. psittaci, C. avium, C. gallinacea and Candidatus C. ibidis using species-specific real-time PCR assays. 243 While still in guarantine, all 15 birds were re-sampled (id 11-324) and 10 of them tested positive for Chlamydiaceae, 244 with a mean Cq value of 36.8 (Table 1). Using BLASTN search, the 16S rRNA gene sequence of one of the high-titer 245 samples (11-261_B096) showed highest identity (97%) to an uncultured Chlamydiales bacterium (clone 122) detected 246 from a seabird. Unfortunately, no isolate was recovered from these sample sets. In 2014, another 37 captive flamingos 247 (Phoenicopterus roseus) from the Paris Zoo (id 14-1167) were sampled, with only one detected as a weak positive 248 (Table 1).

249

250 Detection of atypical chlamydiae in wild flamingo chicks

In France, catches of juvenile flamingos for banding are organized on a yearly basis. Between 2012 and 2015, 404 birds were submitted to cloacal swabbing. PCR examination of the samples showed 30.9% (125/404) of the birds harboring chlamydiae in their digestive tract (**Table 1**). When re-tested for *C. psittaci*, *C. avium*, *C. gallinacea* and *Candidatus* C. ibidis, none of the samples proved positive. From 5 PCR-positive samples subjected to cell culture, chlamydiae were successfully cultured in three of them: 14-2711_R47 (from Salins d'Aigues Mortes, 2014), 15-2067_050 (Etang du Fangassier, 2015) and 15-2067_099 (Etang du Fangassier, 2015).

257

258 Molecular characterization of the Chlamydiaceae detected in flamingos

To determine the genealogical position of the chlamydiae encountered in the flamingos, nearly complete 16S rRNA gene sequences (964 to 1546 nt) were obtained from eight chlamydia-positive samples. Later, complete 16S and 23S rRNA sequences of the three isolates 14-2711_R47, 15-2067_O50 and 15-2067_O99 were extracted from whole262 genome sequences. The phylogenetic tree inferred from multiple alignments of the 16S rRNA gene sequences shows 263 the flamingo isolates forming a distinct cluster that is clearly separated from the established Chlamydia spp., but still 264 within the family Chlamydiaceae (Figure 1). Numerical analysis revealed that the three flamingo isolates shared less 265 than 96% 16S rRNA identity with the other chlamydial species (Table 2), with the closest genetic relatedness found to 266 Candidatus C. ibidis, i.e. 95.64% identity for isolate 14-2711_R47 and 95.57% for isolates 15-2067_O50 and 15-267 2067_099. Comparison of 23S rRNA gene sequences revealed that the most closely related species was also 268 Candidatus C. ibidis with identities of 95.39% and 95.60% (Table 2). Interestingly, ribosomal sequences of isolates 15-269 2067_050 and 15-2067_099 proved identical, but different from those of 14-2711_R47, with 16S and 23S rRNA 270 identity values of 99.55% and 99.32%, respectively.

- 272

Genome data and comparison with other species of the Chlamydiaceae

273 The three new flamingo isolates were subjected to Illumina and Nanopore sequencing. De novo hybrid assembly of 274 raw reads produced a single scaffold representing the entire chromosome for each of the three isolates. Assembly 275 parameters, such as percentage of mapped reads, error rate and coverage of chromosomes and plasmids are given in 276 Table S2.

277 Basic parameters of whole-genome sequences as compiled in Table 3 are similar to those of the established 278 Chlamydia spp. In particular, the number of CDS identified in isolates 14-2711 R47, 15-2067 O50 and 15-2067 O99 279 are 981, 980, and 983, respectively; G+C values are slightly above 40%, and only one rRNA operon and one plasmid 280 were found. Genome sizes of the flamingo isolates are between 1,182 and 1,195 kbp and thus slightly larger than 281 Chlamydia spp. genomes, except C. pneumoniae (1,225 kbp).

282 The values of average nucleotide identity (ANIb) and tetranucleotide signature correlation index (TETRA) presented in 283 Table 4 confirm that the flamingo isolates are genetically different from currently known Chlamydia spp. For instance, 284 isolate 15-2067_O50 showed ANIb values ranging from 65.70 (C. pecorum E58T) to 66.20 (Cand. C. ibidis 10-1398/6), 285 and TETRA indexes from 0.6294 (C. pneumoniae TW-183^T) to 0.8379 (Cand. C. ibidis 10-1398/6). Typical values 286 between members of the genus Chlamydia are in the range from 66.76 (C. suis SWA-2 vs. C. pecorum E58^T) to 92.58 287 (C. psittaci 6BC^T vs. C. abortus S26/3) and 0.7106 (Cand. C. ibidis 10-1398/6 vs. C. pneumoniae TW-183^T) to 0.9864

- 288 (C. gallinacea 08-1274/3^T vs. C. avium 10DC88^T).
- 289 As this distant relatedness raised the question of whether the flamingo strains could belong to a distinct genus, further 290 analyses were performed. The percentage of conserved proteins (POCP) ranged from 66.55 (15-2067_O99 vs. C. 291 pneumoniae TW-183^T) to 71.29 (14-2711 R47 vs. C. pecorum E58^T) (Table 5, upper triangle), confirming the previous 292 findings on the genetically distant position of the three isolates compared to currently known Chlamydia spp., as well as 293 near genetic identity of isolates 15-2067_050 and 15-2067_099. Another parameter tested to assess the taxonomic 294 rank of these new isolates was the average amino acid identity (AAI). Previous findings [21, 27] indicated that, 295 preponderantly, organisms grouped at genus level share between 60 and 80% AAI and are clearly distinguishable from 296 those grouped at species level, which display more than 85% AAI. As can be seen from Table 5, lower triangle, isolate
- 297 14-2711 R47 compared to isolates 15-2067 O50 and 15-2067 O99 shows 80.45 and 80.51% AAI, respectively. The

three isolates share less than 60% AAI with the members of genus *Chlamydia*, while closely related isolates 15-2067_050 and 15-2067_099 are at 99.58% AAI.

300 These data are also supported by genome analysis using a classification scheme recently proposed for members of 301 the order Chlamydiales [36]. In this scheme, the percentage of amino acid sequence identity is calculated for nine 302 conserved gene products (RpoN, FtsK, PepF, Adk, HemL, DnA, SucA, protein_325 and Fabl) extracted from the 303 proteome sequences of the flamingo isolates and the other 11 chlamydial species, plus Candidatus C. ibidis and seven 304 non-Chlamydiaceae. The phylogenetic tree based on these nine proteins in Figure 2 clearly indicates that the flamingo 305 isolates are clustered in a single clade (bootstrap value 100%) that is clearly separated from the main clade harboring 306 all known members of the genus Chlamydia. Within the flamingo clade, isolate 14-2711_R47 forms its own branch 307 apart from 15-2067 O50 and 15-2067 O99 (bootstrap value 100%). Pairwise amino acid identity of the three flamingo 308 isolates (Table S3) shows that they belong to the family Chlamydiaceae with values above cut-off for the 16S rRNA 309 and 23S rRNA, but clearly outside the genus Chlamydia, as indicated by low sequence homologies of the protein 325 310 (56.75 to 61.91%), DnaA (58.70 to 62.17%), SucA (55.20 to 59.55%) and FabL (74.58 to 82.27%) proteins with their 311 homologs in the genus Chlamydia. In contrast, isolate 14-2711_R47 shares low sequence similarities of the RpoN, 312 PepF, Adk and FtsK proteins with the isolates 15-2067_O50 and 15-2067_O99, thus suggesting that they represent 313 different species. Finally, the two nearly identical isolates 15-2067 O50 and 15-2067 O99 share 100% amino acid 314 identity for most of the taxonomically relevant proteins, except for SucA and FtsK (99.79% and 99.76% identity, 315 respectively), indicating that they belong to the same species.

316 Further comparative genome analysis of the flamingo isolates and type strains of 11 members of the genus Chlamydia 317 plus Candidatus C. ibidis included the use of UpSetR, a software package for visualization of shared and unique 318 genomic items (Figure 3). While the new strains share a core genome of 756 genes with the species of the genus 319 Chlamydia, a set of 110 genes, roughly 11 % of their coding capacity, is exclusively encountered in the three flamingo 320 strains. In addition, 29 genes are present only in strains 15-2067_050 and 15-2067_099, and another 31 genes are 321 unique to strain 14-2711 R47. This illustrates the separate genetic position of the three flamingo isolates apart from 322 the genus Chlamydia, and also the close relatedness of strains 15-2067 O50 and 15-2067 O99 as well as their 323 distinction from 14-2711_R47 within the new entity.

324 Moreover, plasmids sized 6,358 bp, 6,320 bp and 6,319 bp were found in strains 14-2711_R47, 15-2065_O50 and 15-

325 2067_099, respectively. The phylogenetic tree in **Figure S1** shows a distinct clade containing the flamingo isolates at

326 a bootstrap value of 100. Comparison of linearized plasmids revealed completely conserved synteny in all three

327 flamingo strains but in comparison with the *C. psittaci* plasmid, the integrase pGP7-D gene is missing (**Figure S2**).

All flamingo strains possess one copy of a full-length *omp*A with 56.10 to 58.82 % nucleotide sequence similarity (53.47 to 55.86 % aa similarity) to *C. pneumoniae ompA* as its closest relative (**Tables S4 and S5**). Among *Chlamydia* spp. these minimal similarity values are at 64.02% (*C. gallinacea ompA* vs. *C. suis*) and, at aa level, 62.44% (*C. pecorum* vs. *C. suis*). In addition, all flamingo strain genomes were found to harbor a group of truncated OmpA-like porins (n=15, 5 or 9) that are arranged in two clusters and lack the N-terminal conserved domain of the chlamydial major outer membrane proteins (MOMPs). Their sequences are variable, but they share the general OmpA/MOMP 334 structure of alternating variable and conserved domains (Figure S3). Among these items, nucleotide sequence 335 similarities to C. pneumoniae ompA are typically 40-55% (35 to 50% at aa level), while individual OmpA-like proteins of 336 the same strain share less than 80% sequence similarity (data not shown). To rule out the possibility of truncated 337 ompA-like genes being due to assembly artifacts, we mapped the ONT read data to the corresponding hybrid 338 assemblies using minimap2 with parameter settings specific for ONT long-reads. Figure S4 provides a schematic 339 overview of selected Nanopore long reads spanning the region of interest with multiple copies of ompA-like genes, 340 exemplary for strain 15-2067_O99 and thus providing strong evidence for the correctness of the assembly. In addition, 341 we performed draft assemblies only based on the ONT long-reads to avoid misassemblies derived from an initial short-342 read graph (as used in the hybrid-approach in Unicycler). As in the hybrid-assembly approach, we also observed 343 multiple ompA-like genes in these long-read-based assemblies (data not shown).

344

345 Morphological features of flamingo isolate 14-2711_R47

346 In BGM-cell culture samples collected at 24h p.i., no chlamydial structures were detected in TEM images. At 48h p.i. inclusions were present in a few cells. Infected cells were either of elongated and slender or round shape (Figure 4A). 347 348 The cytoplasm of infected cells was replaced with inclusions that were incompletely separated by thin strands of 349 cytoplasm (Figure 4A, B). These may either represent multiple inclusions or a large convoluted inclusion. Aggregates 350 of small round electron-dense elementary bodies (EBs, 190-290 nm), aggregates of large, pleomorphic or elongated, 351 less electron-dense reticulate bodies (RBs, 580-780 x 190-580 nm), and mixed aggregates were observed in the same 352 cell (Figure 4A, B). Overall, EBs predominated at 48h p.i., but there were a few cells with multiple inclusions containing 353 predominantly RBs (Figure 4C). Intermediate bodies (IB) with a central electron-dense core, as seen in Chlamydia 354 spp., were not detected. In some cells, vacuoles with flocculate material were located adjacent to inclusions. 355 Comparable vacuoles were also present in non-infected cells. At 72h p.i., inclusions were present in numerous cells. 356 Most infected cells were slender and elongated. The morphology of inclusions was similar to that described at 48h p.i. 357 and both cells with predominantly EBs as well as with RBs were seen (Figure 4D). EBs were round, and RBs 358 appeared elongated or pleomorphic (Figure 4D, E, F). Vacuolization of cells was more pronounced than at 48h p.i. 359 (Figure 4E). In many cells, areas of debris and membrane whirls were present between aggregates of EBs and RBs 360 (Figure 4E, F).

361

362 Morphological features of chlamydial isolate 15-2067_050

363 As above, chlamydial inclusions were not seen in BGM-cell culture at 24h p.i., At 48h p.i., inclusions appeared in a few 364 cells that were often round and contained large vacuoles (Figure 5A). A few bacteria were present within those 365 vacuoles and many spread throughout the remaining cytoplasm (Figure 5A). Whirls of membranes that might 366 represent disintegrated bacteria (empty shells) or cellular organelles were identified in some of the cells (Figure 5B). 367 EBs predominated at that stage (Figure 5C), but there were also a few cells containing predominantly RBs (Figure 368 5D). EBs were round to crescent-shaped and had a wide periplasmic space (Figure 5C), RBs were pleomorphic or 369 elongated (Figure 5B, D). Again, no intermediate bodies (IB) with a central electron-dense core were found. At 72h 370 p.i., chlamydial bodies were present in numerous cells that were often rounded. Numerous EBs and RBs were evenly distributed throughout the cytoplasm (Figure 5E). Small groups or single bacteria were separated by thin strands of
cytoplasm (Figure 5F). EBs (190 – 290 nm) were of variable electron density. Wide periplasmic spaces separated cell
wall and cytoplasm of EBs. EBs displayed a highly variable morphology ranging from round to crescent-shaped to
irregular. RBs (580 -780 nm x 190 – 390 nm) were less electron dense than EBs and pleomorphic or elongated (Figure
5F). In many cells, vacuoles of various sizes were observed in the cytoplasm.

376

377 Detection assays for the new genus and the new species

378 A specific real-time PCR assay for the new genus comprising the flamingo strains described in this study was 379 developed based on the 16S rRNA gene locus (see Materials and Methods). This locus is well characterized for 380 organisms of the order Chlamydiales and contains specific targets for most, if not all, genera. To validate the assay, 381 DNA aliquots of C. abortus, C. avium, C. caviae, C. gallinacea, C. felis, Candidatus C. ibidis, C. muridarum, C. suis, C. 382 trachomatis C. pecorum and C. psittaci strains and all samples positive in Chlamydiaceae-specific real-time PCR of 383 this study were run using the present protocol. The experiments revealed 115 positive samples out of 136 384 Chlamydiaceae-PCR positives. Those 21 samples classified as negative (below detection limit) still had Cq values 385 ranging from 37.10 to 39.97 (Table1).

The same DNA aliquots were tested against newly developed real-time PCRs to detect the new species comprising a) strain 14-2711_R47^T or b) strains 15-2065_O50^T and 15-2067_O99, respectively. These two assays proved more sensitive than the genus-specific PCR as we detected among the 21 negatives four more positive samples for the former and two for the latter new species. Interestingly, four samples from the preliminary investigation showed a positive signal for both species, possibly indicating dual infection.

391 The test results yielded detection rates of 9.6% (13/136) and 86.8% (118/136) for a) and b), respectively (Table 1).

- 392
- 393

394 Discussion395

396 The present study was undertaken as part of the routine precautionary biosafety measures to protect birds in a large 397 aviary. To reduce the risk of infection(s), it is mandatory for new entries to undergo appropriate diagnostic testing and 398 quarantine. When a group of quarantined Chilean Flamingos destined to be integrated into a large aviary complex was 399 examined, Chlamydiaceae-positive individuals were identified. These initial findings prompted further samplings in this 400 group, as well as in another group of captive Greater Flamingos from another zoo and in wild Greater Flamingos. 401 Altogether, 52 captives and 404 wild birds were sampled yielding a PCR-based Chlamydiaceae prevalence of 21.1 and 402 30.9%, respectively. Notably, the usual avian chlamydial species, i.e. C. psittaci, C. avium and C. gallinacea were 403 absent in these birds. In further testing of Chlamydiaceae-positive samples, newly developed real-time PCR assays 404 revealed detection rates of 86.8% for a new species represented by flamingo isolates strains 15-2067_O50 and 15-405 2067_O99 and 9.6% for another new species comprising strain 14-2711_R47.

All chlamydia-positive flamingos in the present study were visually found to be in good health, independently of their
 habitat (captive or wild). Therefore, we hypothesize that chlamydiae of the new taxa behave as (gastro-intestinal)
 commensal bacteria in healthy birds. Further investigations are required to find out whether they bear the potential of

409 causing disease under specific circumstances as is the case with other avian members of the *Chlamydiaceae*. Future
 410 studies will also have to show whether flamingos are the only natural host of these new agents.

411

412 The 16S rRNA sequences from captive and wild flamingos were highly similar to a sequence detected in a seabird that 413 had been caught in the Behring Sea (Uncultured Chlamydiales bacterium clone 122, from a glaucous-winged gull [3]), 414 as well as to sequences from seabirds sampled from common murres (12-3998_AO053 and 12-3998_AO018) and a 415 European herring gull (12-1761_J072) in France [1]. Closely related non-classified Chlamydiaceae were also 416 sporadically detected in two flocks of farmed ducks [15], thus suggesting that, even though encountered only 417 temporarily at one farm, these chlamydiae are not confined to seabirds. All 16S rRNA sequences from cultured and 418 uncultured flamingo specimens formed a distinct clade outside the genus Chlamydia, but within the family 419 Chlamydiaceae. The above-mentioned Uncultured Chlamydiales bacterium clone 122 and other seabird specimens 420 proved to be their closest relative (Figure 1).

421 According to currently accepted rules, "sequence identity of 94.5% or lower for two 16S rRNA genes is strong evidence 422 for distinct genera" [53], this suggests that the present flamingo isolates should be assigned to a new genus. In this 423 context, POCP has become a widely accepted parameter for delimiting genus boundaries in prokaryotic genome-424 based taxonomy. It involves comparison of proteome sequences including all proteins of a species or strain, and a 425 POCP value of 50% was proposed as a genus boundary [37]. This means that two strains would share less than half of 426 their protein repertoires if they belong to different genera. Here, POCP values determined for the flamingo isolates 427 proved considerably higher than the 50% cut-off (Table 5), thus impeding formal introduction of a separate genus in 428 the family Chlamydiaceae. However, this parameter has been used by microbiologists and taxonomers for only five 429 years, so that there is little or no experience on the possibility of a more flexible use of the cut-off in particular cases. At 430 the same time, the average amino acid identity (AAI) has been used since 2005 [21] and is considered a robust 431 measure of genetic relatedness between two strains. The values ranging from 55.30 to 56.54% for the flamingo strains 432 are clearly below the recommended level of approximately 70% for genus boundaries, thus supporting the idea of a 433 separate genus.

434

435 TEM revealed that both isolates 14-2711 R47 and 15-2067 O50 replicated intracellularly and developed EBs and 436 RBs, which is characteristic for the biphasic replication cycle of Chlamydiaceae. Notably, inclusion morphology differed 437 from other members of the genus Chlamydia, e.g. C. psittaci, C. abortus, C. pecorum, C. trachomatis, C. avium, or C. 438 gallinacea. In most late infected host cells, aggregates of bacteria separated by variably thick strands of cytoplasm 439 filled the entire cell. This was interpreted as multiple inclusions fusing and forming large branching inclusions. The 440 inclusion morphology could reflect differences in intracellular trafficking [11]. In addition, no intermediate bodies (IBs) 441 with the characteristic morphology described for the genus Chlamydia were observed alongside EBs and RBs in both 442 type strains. Since differences in inclusion and EB/RB morphology were reported between the various families of 443 Chlamydiales [2, 5, 7, 12-14, 26], between species of Chlamydia [33], and even between isolates of the same species 444 [31], the detection of such morphological distinctions between flamingo strains and other Chlamydiaceae is not entirely

surprising. Within the species of *C. pneumoniae*, wide periplasmic spaces were detected only in the Koala strainLPCoLN, but not the human isolate AR39 [31].

447 Other aspects to be considered when interpreting the particular morphology of strains 14-2711_R47 and 15-2067_O50 448 are treatment prior to fixation [29] and influence by the preparation. Although standardized methods were used, an 449 effect cannot be excluded, since conventional electron microscopy relies on fixation and embedding of samples into 450 resin. Different osmolarities of fixatives and buffers caused changes in morphology, particularly in the family 451 Parachlamydiaceae, with higher osmolarity resulting in shrunken, star-shaped or crescent-shaped EBs [40]. This was 452 interpreted as an indication of a distinct membrane composition or intracellular structure [40]. Crescent-shaped EBs 453 and wide periplasmic spaces were observed in isolate 15-2067_O50 only, although both isolates were treated under 454 identical conditions. Thus, potential differences between the type strains should be explored further. Interestingly, only 455 the metabolically inactive EBs were affected. Whole-cell cryo-electron tomography revealed polarization of the type 3 456 secretion system on EBs during distinct stages of their development [32]. This may increase their susceptibility to 457 deformation. Finally, both strains were cultured in BGM cells, which may not be as optimal as cells from their natural 458 host, the flamingo. Conceivably, this could also have contributed to the differences to classical chlamydial morphology 459 observed here. The influence of culture conditions, e.g. temperature, on inclusion morphology has been demonstrated 460 for various veterinary and human chlamydial species, especially those causing infections in reptiles [33]. Some of the 461 vacuoles and membrane whirls observed in isolates 14-2711 R47 and 15-2067 O50 may represent remnants of 462 degraded bacteria.

463

464 Concerning species assignment, the current recommendation for the genomic circumscription of species by means of 465 pairwise comparison prescribes ANI higher than 96% and TETRA values above 0.999 [38]. While the present isolates 466 15-2076_O50 and 15-2076_O99 seem to belong to the same species (ANI 99.46 and TETRA 0.9997; Table 4), isolate 467 14-2711 R47 shows distinct parameters (e.g. 75.53 and 0.9460 to strain 15-2067 O50), the latter indicating that it 468 probably represents a different species. This notion is confirmed by POCP values of 99.85 for the closely related 469 strains, as compared to 95.41 (14-2711 R47 vs. 15-2076 O50) and 95.26 (14-2711 R47 vs. 15-2076 O99), 470 respectively (Table 5). POCP values between different chlamydial species can be as high as 98.64 (C. psittaci vs. C. 471 abortus) and 96.65 (C. avium vs. C. gallinacea), although it should be noted that the parameter is not regarded valid for 472 species circumscription.

473 The present data from comparative genomic analysis clearly illustrate i) the distinct genetic position of the flamingo 474 strains compared to members of the genus Chlamydia and ii) the nearly identical genome composition of new strains 475 15-2076_O50 and 15-2076_O99 compared to strain 14-2711_R47. While the flamingo strains share 756 homologous 476 CDS, i.e. roughly three-fourths of their genomes, with 12 members of the genus Chlamydia, there is also a 477 considerable portion of 176 CDS occurring only in these three isolates (Figure 3). Besides, the genome of isolate 14-478 2711 R47 harbors 31 unique genes, which illustrates its distinction from the other two flamingo isolates. Based on 479 shared genomic items, no particularly close relationship to certain individual Chlamydia spp. can be derived from these 480 data, which is in accordance with the phylogenetic tree in Figure 2.

481 Analysis of a validated panel of nine conserved taxonomically relevant proteins was also fully in line with the genome 482 data (**Figure 2**), thus suggesting assignment of the three isolates to two different species.

483 In addition, the new strains described here proved distinct from *Chlamydia* spp. by the presence of multiple truncated

484 sequences of *ompA*-like genes besides a 'classical' *ompA*. As this is a completely new finding, possible functions of the

485 truncated proteins, if expressed and translated, have yet to be elucidated. It is conceivable that they could enhance

486 functions known from the main outer membrane protein encoded by *ompA*, i.e. cytoadhesion and immunogenicity, as

- 487 well as contribute to the bacterium's outer membrane stability.
- 488

490

489 Compilation of the main characteristics and distinctive features between the present flamingo strains and the

organisms classified in the genus Chlamydia (Table 6) clearly illustrates the separate taxonomic position of the former.

- 491 Therefore,
- 492 we propose the introduction of a new genus Chlamydiifrater gen. nov. with two new species, i.e. Chlamydiifrater
- 493 phoenicopteri sp. nov. with type strain 14-2711_R47^T and Chlamydiifrater volucris sp. nov., with strains 15-2067_O50^T
- 494 (type strain) and 15-2067_099. The formal proposal of the new genus and species is given in the protologue (Table 7).

- 528 Figure 4: BGM cells infected with Chlamydiifrater phoenicopteri strain 14-2711_R47^T for 48 hours (A, B, C) and 72
- 529 hours (D, E, F). (A) Infected cells are elongated and slender Most of the cytoplasm is filled by either multiple confluent
- 530 chlamydial inclusions or one large branching inclusion. EB predominate. (B) Higher magnification of (A): thin strands of
- 531 cytoplasm (dotted lines, examples) extend between aggregates of bacteria. Some aggregates consist predominantly of
- 532 EBs (E), some of RBs (R), and some of both EBs and RBs (M). (C) Cell with multiple inclusions (outlined by dotted

533 lines) that contain predominantly RBs. RBs are pleomorphic. (D). Adjacent infected cells may contain predominantly

534 RBs (1) or EBs (2). Both cells are elongated. The cytoplasm is replaced with numerous bacteria. Delicate strands of

535 cytoplasm separate aggregates of bacteria. (E) Vacuole (V) with flocculate material adjacent to inclusions with EBs (E)

536 and RBs (R). Some RBs are particularly slender and elongated (arrowheads). The cytoplasm between inclusions

537 contains small vacuoles, membrane whirls and cellular debris (D). (F) Higher magnification of EBs (E, examples), RBs

- 538 (R, examples) and cellular debris (D) in an infected cell. RBs are elongated (L) and pleomorphic (P). Bar in A = 2 µm,
- 539 bars in B-F = 1 μ m.
- Figure 5: BGM cells infected with *Chlamydiifrater volucris* strain 15-2067_O50^T for 48 hours (A, B, C) and 72 hours (D,
 E). (A) Infected cell with large vacuoles (V) containing a few EBs and with numerous bacteria throughout the cytoplasm.
- 543 (B) Inclusions with predominantly EBs and few RBs (R). Some EBs are crescent-shaped (arrowheads, examples) and 544 some have wide periplasmic spaces (arrows, examples). (C) RBs predominate in a few cells. RBs are separated by 545 strands of cytoplasm. RBs are pleomorphic to elongated (L). (D) Higher magnification of EBs (E), RBs (R) and whirls of 546 membranes (arrows, examples) within a cell. (E) Confluent inclusions fill the cytoplasm of an infected cell. Both EBs 547 and RBs are present. (F) Higher magnification of EBs and RBs in an infected cell. EBs are round to crescent-shaped 548 (arrowheads, examples) and have a wide periplasmic space (arrows, examples). RBs are pleomorphic (P) or elongated 549 (L). Bacterial aggregates are separated by delicate strands of cytoplasm (dotted lines, examples). Bars in A, E = 2 µm, 550 bars in B, C, D, F = 1 μ m.

553 Acknowledgments

554 Sampling of flamingos was performed in collaboration with the research center Tour du Valat in the framework of 555 annual catches for ring identification organized by Arnaud Béchet. We are particularly thankful to Olivier Yvernogeau 556 (Genindexe) for sharing DNA samples from flamingos for initial analysis. The authors would also like to thank Lisa Wolf 557 and Jana Jagiela for excellent preparation of samples for electron microscopy and Wolfram Maginot for his excellent 558 photographic assistance. Martin Hölzer appreciates the support of the Joachim Herz Foundation by the add-on 559 fellowship for interdisciplinary life science.

Genus name	Chlamydiifrater		
Species name	-	Chlamydiifrater phoenicopteri	Chlamydiifrater volucris
Taxon status	gen. nov.	sp. nov.	sp. nov.
Etymology	Chla.my.di.i.fra'ter. N.L. fem. n. <i>Chlamydia</i> a bacterial genus; L. masc. n. <i>frater</i> brother; N.L. masc. n. <i>Chlamydiifrater</i> brother of <i>Chlamydia</i>	phoe.ni.co.pte'ri. N.L. gen. n. phoenicopteri of Phoenicopterus	vo.lu'cris. L. gen. n. volucris of a bird
Type species of the genus	Chlamydiifrater phoenicopteri	-	-
Description of the new taxon and diagnostic traits	All members of the genus are obligate intracellular bacteria with a Gram-negative type cell wall. They follow a biphasic developmental cycle of generally longer duration compared to members of the related genus <i>Chlamydia</i> . Along this cycle, inclusions harbor electron- dense, infective elementary bodies, which transform into electron-lucent, metabolically active and replicating reticulate bodies. Intermediate bodies are scarce or absent, at least in the early and middle phases of the cycle. <i>Chlamydiifrater</i> spp. possess a circular genome sized in the order of 1.2 Mbp. Members of this genus are distinguished from <i>Chlamydia</i> spp. and other taxa of the family <i>Chlamydiaceae</i> by their ribosomal RNA sequences (less than 96% 16S and 23S rRNA sequence identities) and the following genomic parameters: ANI (< 67%), Tetra (< 0.84), AAI (< 57%), and POCP (< 72%).	The only currently known host of <i>Chlamydiifrater phoenicopteri</i> is the flamingo (<i>Phoenicopterus roseus</i>). The bacterium can be recovered from the contents of the cloaca. Natural routes of transmission have yet to be investigated, but, analogous to most other chlamydiae, airborne transmission through aerosolized dry feces and dust particles seems likely. From the observations made so far, <i>Chlamydiifrater phoenicopteri</i> seems to be a commensal agent. The potential for a facultative pathogenic role and zoonotic infection of humans is unknown. <i>Chlamydiifrater phoenicopteri</i> strains can be grown in cell culture or embryonated chicken eggs. Their growth is characterized by a biphasic developmental cycle, which is encountered in the other chlamydial organisms as well. Elementary bodies and pleomorphic reticulate bodies are distributed in numerous confluent inclusions throughout the cells. Members of the species can be specifically identified using real-time PCR targeting the rpoN (RNA polymerase sigma-54 factor) gene locus. In addition, strains of the species can be identified using 16S rRNA gene sequence analysis.	All strains of <i>Chlamydiifrater volucris</i> isolated so far originated from the flamingo (<i>Phoenicopterus roseus</i>). The bacterium can be recovered from the contents of the cloaca. Natural transmission routes have yet to be investigated, but, analogous to most other chlamydiae, airborne transmission through aerosolized dry feces and dust particles seems possible. It appears likely that <i>Chlamydiifrater volucris</i> is a commensal agent in wild birds. The potential for zoonotic infection of humans is unknown. <i>Chlamydiifrater volucris</i> strains can be grown in cell culture or embryonated chicken eggs. Their growth is characterized by a biphasic developmental cycle, which is encountered in <i>Chlamydia</i> spp. and other members of the order <i>Chlamydiales</i> . Elementary bodies and pleomorphic reticulate bodies are distributed in numerous confluent inclusions throughout the cells. Strains belonging to this the species can be specifically identified using real-time PCR targeting the rpoN (RNA polymerase sigma-54 factor) gene locus. In addition, they can be identified by their 16S rRNA gene sequences.
