INTRODUCTION & OBJECTIVES

- Foot-and-mouth disease is a highly contagious disease affecting wild and domestic artiodactyls, caused by a Picornavirus named Foot-and-mouth disease virus (FMDV).
- FMDV is able to persist (i.e. infectious virus detected after 28 days post-infection (dpi)) for several years in the pharyngeal epithelium of ruminants after resolution of clinical signs¹. However, this is not the case in pigs where only viral RNA could be detected in vivo for more than 60 dpi in the oropharyngeal tonsils and dorsal soft palate^{2,3}.
- No porcine cell model from a tissue of interest is currently available.

➤ **Aim of the study:** To develop a specific cellular model to study FMDV infection in porcine cells.

Workflow

- Swine oropharyngeal tonsils and dorsal soft palate (DSP) were sampled.
- Epithelial structures were identified and isolated ①.
- Epithelial cells derived from DSP were propagated in monolayers, characterized ②, then infected with FMDV ③.
- Epithelial cells were then grown in multilayers at the air-liquid interphase to mimic a pluristratified epithelium ④.

② DSP cells characterization

- DSP cells were cultured in monolayers, fixed, then labelled with antibodies targeting epithelial markers (occludin, cyokeratin), fibroblastic markers (vimentin) and FMDV receptor ($\alpha_v\beta_6$ integrin).

- Significant expression of occludin was detected, indicating an epithelial nature.
- Greater expression of vimentin than cyokeratin was detected, indicating an epithelial-mesenchymal transition.
- High expression of the major receptor for FMDV was detected.

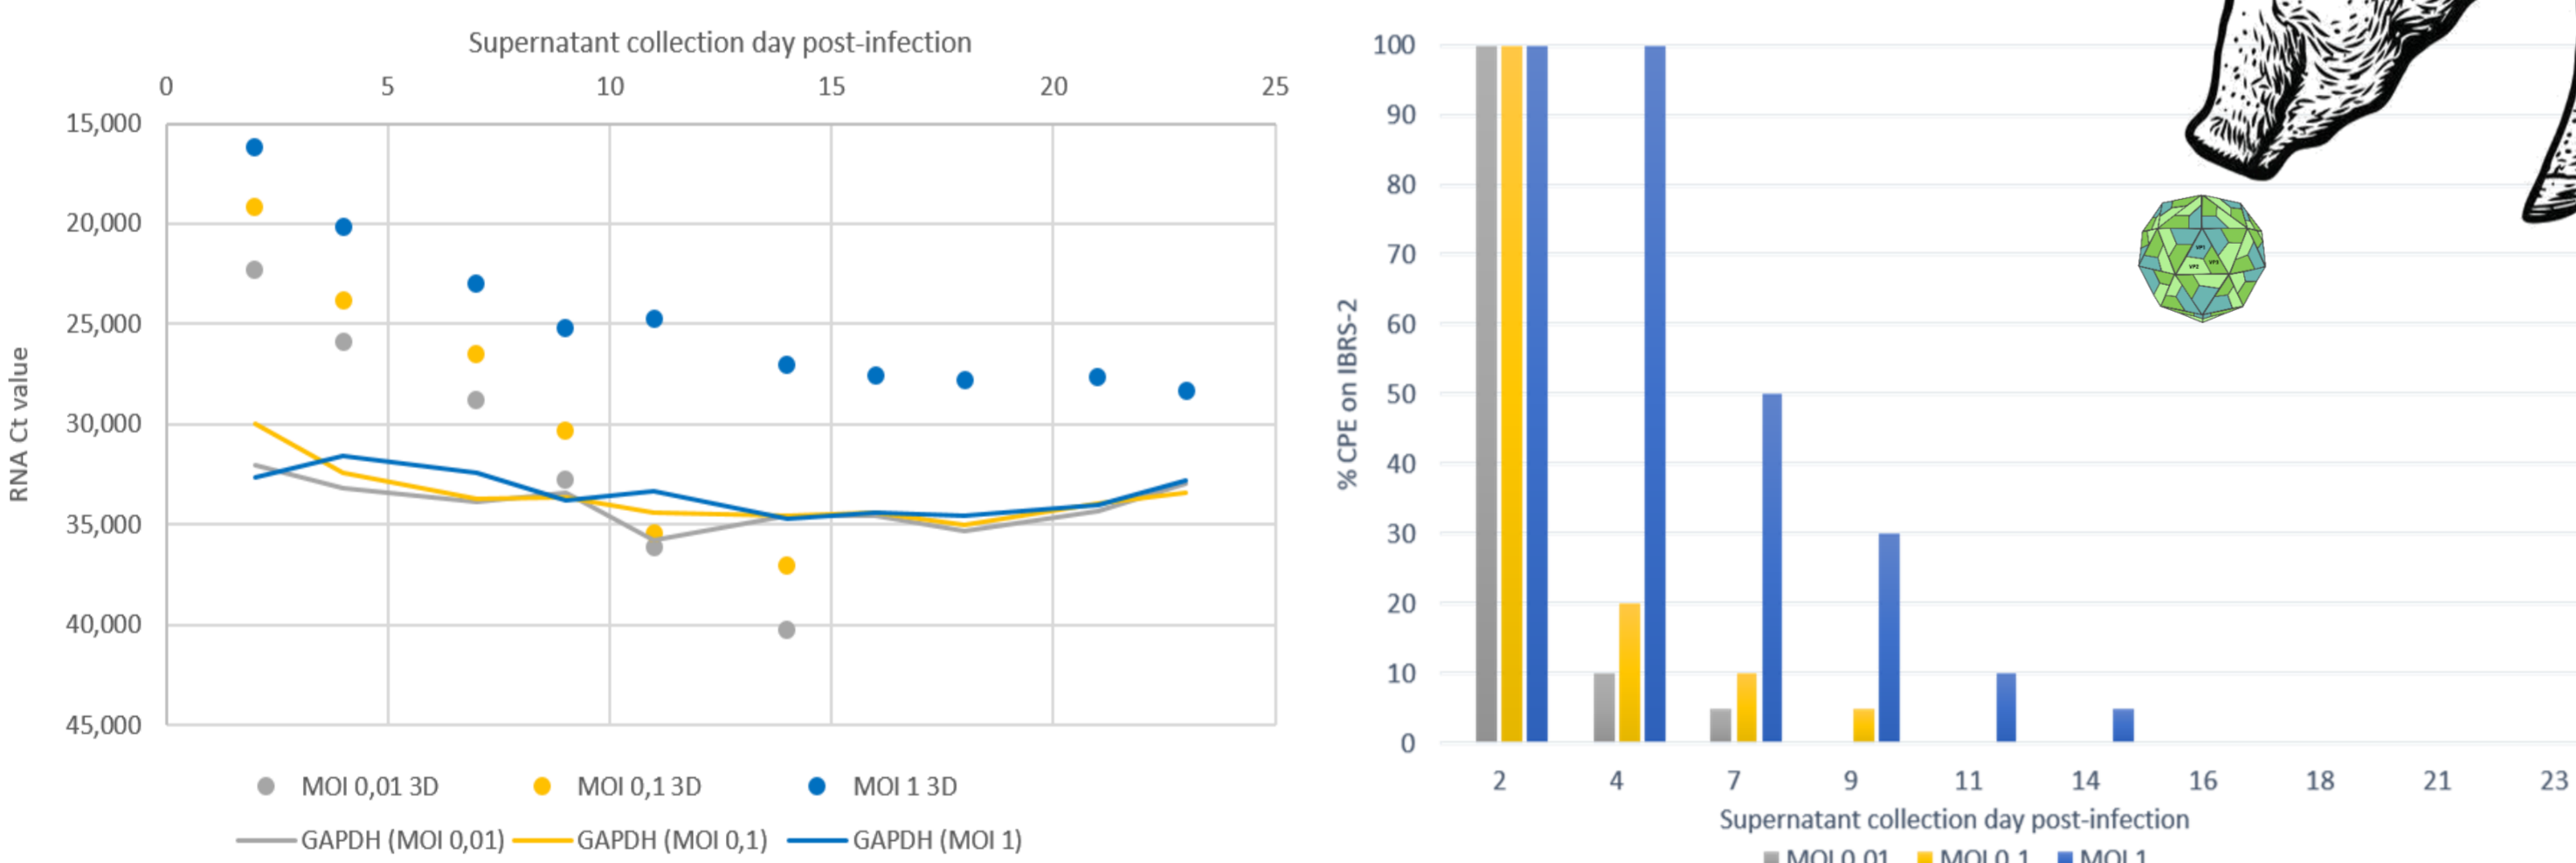

① Epithelial structures characterization

- Oropharyngeal tonsils and DSP samples were stained using HES (hematoxylin-eosin-saffron) in order to localize epithelial structures.
- Epithelium were identified in both oropharyngeal tonsils and DSP samples

③ Infection of DSP monolayers

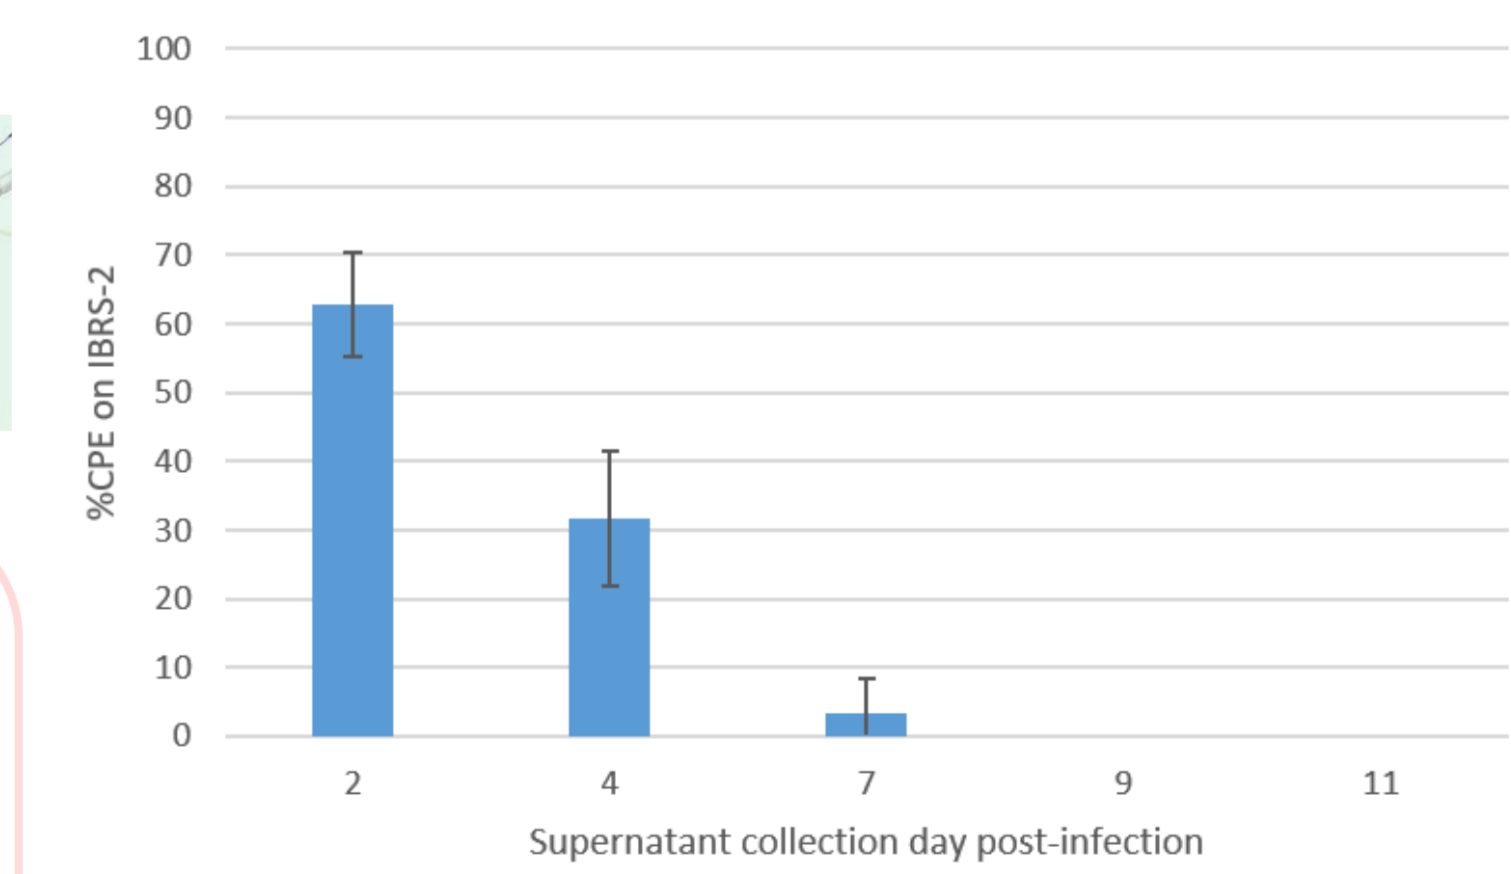

- DSP cells were grown in monolayers and infected with a type-O FMDV at three multiplicity of infection (MOI 0.01; 0.1; 1).
- Culture supernatants were collected every two or three days for 112 dpi and analyzed for infectious virus, antigens and viral RNA.

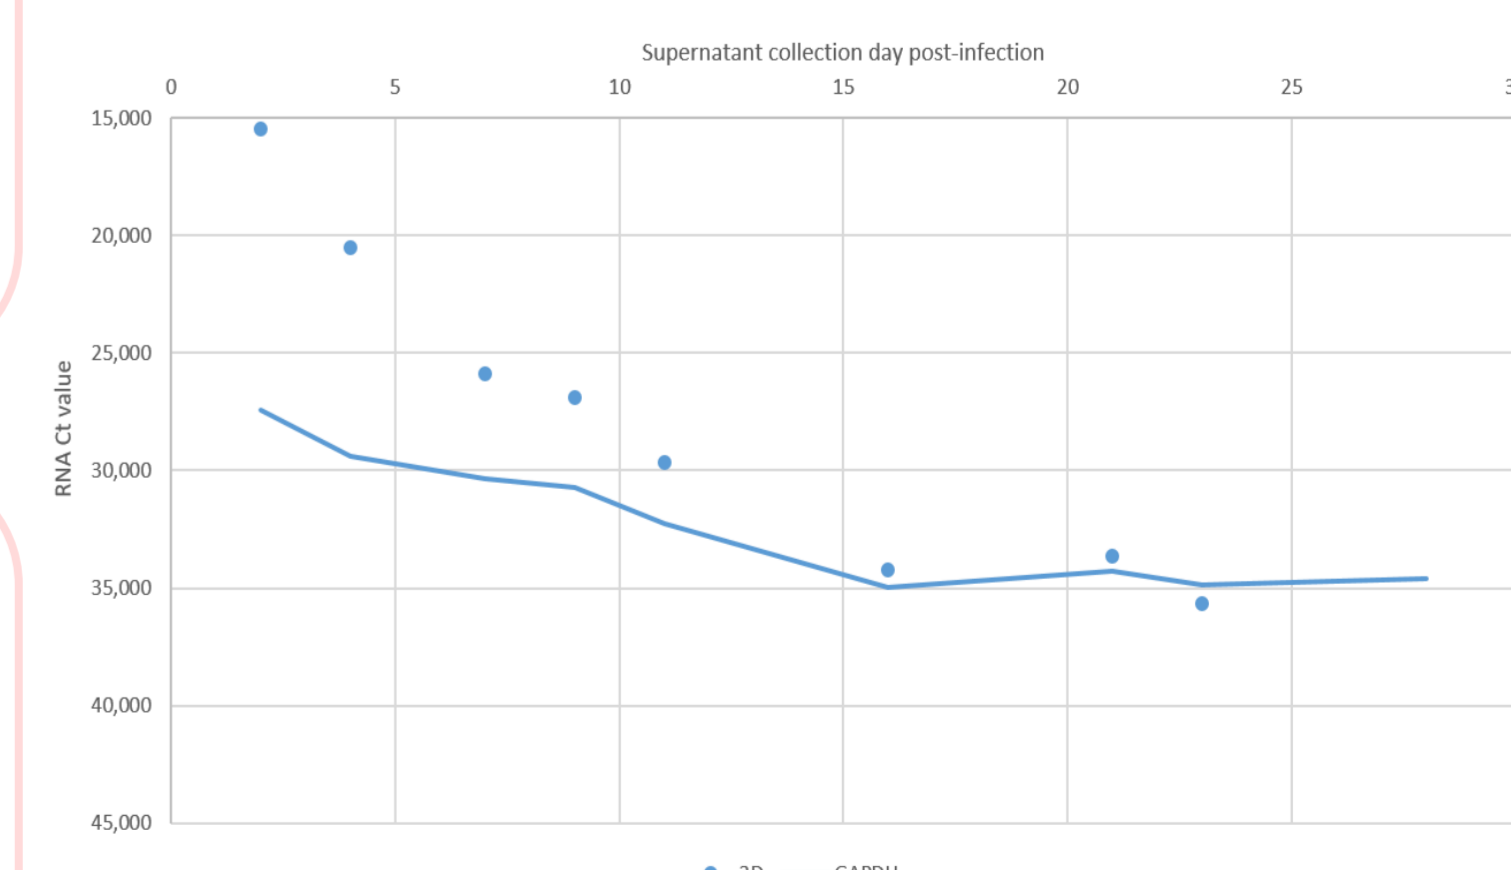

- MOI 1 was considered as the optimal infection condition for porcine DSP cells.
- Infectious virus were detected by viral isolation up to 14 dpi in culture supernatants.
- Viral antigen were detected up to 16 dpi by immunofluorescence.
- Viral RNA were detected up to 60 dpi by RTqPCR..

④ Infection of DSP multilayers

- DSP cells were grown in multilayers, on collagen membrane, at the air-liquid interface and then infected with a type-O FMDV at MOI 1.
- Culture supernatants were collected every two or three days for 39 dpi and analyzed for infectious virus, antigen and viral RNA.

- Multilayer depth was determined using HES staining.
- Infectious virus were detected by virus isolation up to 7 dpi in culture supernatants.
- Viral antigen were detected up to 9 dpi by immunofluorescence.
- Viral RNA were detected up to 23 dpi by RTqPCR.

Conclusion & perspectives

- We have succeeded in developing a primary porcine dorsal soft palate cell model susceptible to FMDV infection.
- A similar model based on oropharyngeal tonsil cells, could not be developed since these cells did not maintain in culture.
- Consistent with what has been observed in vivo in pigs, no evidence of FMDV persistence could be detected in our cell model (no infectious virus detected after 28 dpi).

- Porcine DSP cells could be immortalized to obtain a cell line suitable for FMDV research and diagnosis.
- These cells could constitute a privileged tool in the differential diagnosis of FMDV, if susceptible to the other viruses.
